Cyp2c44 Epoxide Is Essential for Preventing the Renal Sodium Absorption During Increasing Dietary Potassium Intake

Peng Sun, Joseph Antoun, Dao-Hong Lin, Peng Yue, Katherine H. Gotlinger, Jorge Capdevila, Wen-Hui Wang

Abstract—The aim of this study is to test whether the Cyp2c44 epoxide-dependent metabolism of arachidonic acid prevents the hypertensive effect of a high K (HK) intake by inhibiting the epithelial sodium channel (ENaC) activity. A HK intake elevated Cyp2c44 mRNA expression and 11,12-epoxycosatrienoic acid levels in the cortical collecting duct in Cyp2c44(+/+) mice (wild-type [wt]). However, an HK intake failed to increase 11,12-epoxycosatrienoic acid formation in the cortical collecting ducts of Cyp2c44(−/−) mice. Moreover, increasing K intake enhanced arachidonic acid–induced inhibition of ENaC in the wt but not in Cyp2c44(−/−) mice. In contrast, 11,12-epoxycosatrienoic acid, a Cyp2c44 metabolite, inhibited ENaC in the wt and Cyp2c44(−/−) mice. The notion that Cyp2c44 is the epoxide responsible for mediating the inhibitory effects of arachidonic acid on ENaC is further suggested by the observation that inhibiting Cyp-epoxide inhibited the whole-cell Na currents in principal cells of wt but not in Cyp2c44(−/−) mice. Feeding mice with an HK diet raised the systemic blood pressures of Cyp2c44(−/−) mice but was without an effect on wt mice. Moreover, application of amiloride abolished the HK-induced hypertension in Cyp2c44(−/−) mice. The HK-induced hypertension of Cyp2c44(−/−) mice was accompanied by decreasing 24-hour urinary Na excretion and increasing the plasma Na concentration, and the effects were absent in wt mice. In contrast, disruption of the Cyp2c44 gene did not alter K excretion. We conclude that Cyp2c44 epoxide mediates the inhibitory effect of arachidonic acid on ENaC and that Cyp2c44 functions as an HK-inducible antihypertensive enzyme responsible for inhibiting ENaC activity and Na absorption in the aldosterone-sensitive distal nephron. Key Words: 11,12-EET ■ arachidonic acid ■ ENaC ■ hypertension ■ kidney

Increasing the dietary K intake has been reported to prevent the high salt intake–induced hypertension in both humans and rats. The guideline published in a Dietary Approaches to Stop Hypertension diet recommends all healthy adults to double their daily K intake to prevent salt-sensitive hypertension. However, the underlying mechanisms by which a high K (HK) intake prevents the salt-sensitive hypertension are not completely understood. Factors such as kallikrein and prostaglandins have been suggested to play a role in decreasing blood pressure and increasing renal Na excretion. Our previous study demonstrated that an HK intake stimulated the kidney expression of the rat Cyp2c23 epoxide, a homologue of the murine Cyp2c44 epoxide. A large body of evidence indicates that CYP2C epoxide–dependent arachidonic acid (AA) metabolism plays an important role in preventing the salt-sensitive hypertension. Inhibition of renal CYP2C epoxideases caused hypertension in rats on high-Na diets. However, the animals became normotensive after the removal of the epoxidease inhibitor, even when the animals were kept on a high-Na diet. The role of the epoxide in preventing salt-sensitive hypertension was best demonstrated in the Cyp4a10(−/−) mouse model. Although Cyp4a10 does not metabolize AA to epoxyeicosatrienoic acids (EETs), disruption of the Cyp4a10 gene reduced the expression of epoxidease, such as Cyp2c44, and resulted in salt-sensitive hypertension. However, the identity of the antihypertensive epoxide isoform(s) is not unambiguously determined. Because Cyp2c44 homologues are epoxide isoforms responsible for 11,12-EET biosynthesis in the kidney and their expression is upregulated by an HK intake, we tested whether the Cyp2c44-dependent metabolism of AA plays a role in mediating the antihypertensive effects of an HK intake.

Methods

Animals and Metabolic Cage
Isogenic Cyp2c44(−/−) and Cyp2c44(+/+) mice were obtained from J.C. (see the supplemental Methods section for details). We
also purchased 129svE mice (black Agouti coat), a strain of the 129svJ mice from Taconic Farms (Germantown, NY), isogenic with the animals from Vanderbilt University. Mice were fed solid diets containing normal (1.0% KCl) or a high K (2.5% KCl). Disruption of Cyp2c44 reduced total EET/dihydroxyeicosatrienoic acid (DHET) excretion in the urine. However, the ratio among 8,9-, 11,12-, and 14,15-EET/DHET was similar between Cyp2c44(+/−) mice (please see Figure S1, available in the online Data Supplement at http://hyper.ahajournals.org). Moreover, Western blot analysis demonstrated that expression of Cyp2c44 and 11,12-EET level in the isolated CCDs of Cyp2c44(+/−) mice (wt) and of Cyp2c44(−/−) mice on an NK and an HK diet for 1 week. *Significant difference between 2 groups.

Figure 1. A, A Western blot showing the effect of K diet on the expression of Cyp2c44 in the renal cortex and outer medulla (mixture) of wild-type (wt) mice on normal K (NK; 1.0% KCl) or high K (HK; 2.5% KCl) for 7 days. B, Effect of K diet on relative expression of Cyp2c44 mRNA in the cortical collecting duct (CCD) of wt mice on a 1.0% K or 2.5% K diet for 1 week. C. Effect of K diet on 11,12-epoxyeicosatrienoic acid (EET) and 11,12-dihydroxyeicosatrienoic acid (DHET) in the isolated CCDs of Cyp2c44(+/−) mice (wt) and of Cyp2c44(−/−) mice on an NK and an HK diet for 1 week. *Significant difference between 2 groups.

Measurement of EET/DHET
We followed the method described previously to measure 11,12-EET/DHET. All of the solvents were high-performance liquid chromatography grade or better, and synthetic standards were used to obtain standard curves (5–500 pg) for each eicosanoid (linear regression R² values >0.99) and internal standard (also see the online Data Supplement).

Measurement of BP
We measured the BP using a carotid artery catheter or noninvasive tail-cuff methods (Kent Scientific, Torrington, CT) between 9:00 and 11:00 AM. For inserting catheter, mice were anesthetized with Nembutal (75 mg/kg of body weight), and the carotid artery was separated from the vagus nerve and muscle. After cutting open the carotid artery, we inserted a polyethylene (PE-10) catheter into the vessel. The catheters were connected to a remote pressure sensor. After the animals became familiar with the environment, their BPs were measured with a Digi-Med Blood Pressure Analyzer (MicroMed Inc, Louisville, KY). The BP of each animal was monitored continuously for ≥40 minutes at an ambient temperature of 23°C, and >20 such measurements were performed to get the mean value. For tail-cuff method, mice were trained for 1 to 2 weeks before the start of experiments. Systolic BP measurements were recorded after 5 cycles of acclimatization, and 7 to 15 measurements were taken as the representative pressure for each mouse.

Solution and Statistics
AA and 11,12-EET were purchased from Cayman Chemicals (Ann Arbor, MI). The antibody for Cyp2c44 was generated from J.C. The data are presented as mean±SEM. We used either Student t test or 1-way ANOVA test to determine the statistical significance. P values ≤0.05 were considered significant.

Results
We demonstrated previously that increasing dietary K content from 1% to 10% stimulated the renal expression of Cyp2c23 (the homologue of mouse Cyp2c44) and 11,12-EET biosynthesis in the isolated CCD of rat kidney. We now examined whether an increase in the dietary K within physiological relevant ranges was sufficient to stimulate Cyp2c44 expres-
CYP2C44+/+ CYP2C44-/-  

Figure 2. A, A single channel recording showing the effect of arachidonic acid (AA) and 11,12- epoxyeicosatrienoic acid (EET) on epithelial sodium channel (ENaC) in the cortical collecting duct (CCD) of Cyp2c44(-/-) mice on a high-K (HK) diet for 3 to 7 days. The experiment was performed in a cell-attached patch, and the holding potential was 60 mV. The channel closed level is indicated by a dotted line and "c." B, Effect of AA on ENaC activity (NPo, a product of channel number (N) and open probability (Po)); top or the normalized channel activity (bottom) in wild-type (wt) and Cyp2c44(-/-) mice. Experiments were performed in cell-attached patches in the split-open CCD of wt and Cyp2c44(-/-) mice. AA was directly added to the bath, and the channel activity was normalized by comparing NPo of wt mice on a control diet. *Significant difference between the experimental group and the corresponding control. #Data were significantly different from the rest of the groups.

Because non-Cyp2c44 epoxygenases are also expressed in the CCD,20 we next examined whether the inhibitory effects of AA on ENaC were Cyp2c44 dependent by analyzing ENaC responses to AA in the CCD dissected from wt or Cyp2c44(-/-) mice fed a control K or HK diet. Figure 2A is a channel recording in a cell-attached patch showing that the application of AA (15 µM) did not inhibit ENaC activity in Cyp2c44(-/-) mice. In 10 similar experiments, the channel activity, defined by NPo (a product of channel number [N] and open probability [Po]), was not significantly different (1.94±0.6) in the presence of or in the absence of AA (10–15 µmol/L; 1.8±0.6; Figure 2B). In contrast, increasing K content from 1.0% to 2.5% enhanced AA-mediated inhibition of ENaC in the wt mice. Data summarized in Figure 2B demonstrate that application of AA (10 µmol/L) inhibited ENaC activity from 0.87±0.04 to 0.4±0.06 (Figure 2B, top) or by 52±5% (Figure 2B, bottom) in the wt mice on a control K diet (N=8) and reduced NPo from 1.9±0.4 to 0.23±0.06 or by 88±10% in the animals fed an HK diet (N=8). The lack of an AA effect on the ENaC activity in Cyp2c44(-/-) mice was attributed to the absence of Cyp2c44 epoxygenase activity, because 100 nmol/L if 11,12-EET (Cyp2c44 AA metabolite) blocked ENaC in the CCD of Cyp2c44(-/-) mice on both control and HK diets (data not shown). These results identify Cyp2c44 as the epoxygenase responsible for the increases in 11,12-EET biosynthesis of the CCD in response to an HK intake.

Because non-Cyp2c44 epoxygenases are also expressed in the CCD,20 we next examined whether the inhibitory effects of AA on ENaC were Cyp2c44 dependent by analyzing ENaC responses to AA in the CCD dissected from wt or Cyp2c44(-/-) mice fed a control K or HK diet. Figure 2A is a channel recording in a cell-attached patch showing that the application of AA (15 µM) did not inhibit ENaC activity in Cyp2c44(-/-) mice. In 10 similar experiments, the channel activity, defined by NPo (a product of channel number [N] and open probability [Po]), was not significantly different (1.94±0.6) in the presence of or in the absence of AA (10–15 µmol/L; 1.8±0.6; Figure 2B). In contrast, increasing K content from 1.0% to 2.5% enhanced AA-mediated inhibition of ENaC in the wt mice. Data summarized in Figure 2B demonstrate that application of AA (10 µmol/L) inhibited ENaC activity from 0.87±0.04 to 0.4±0.06 (Figure 2B, top) or by 52±5% (Figure 2B, bottom) in the wt mice on a control K diet (N=8) and reduced NPo from 1.9±0.4 to 0.23±0.06 or by 88±10% in the animals fed an HK diet (N=8). The lack of an AA effect on the ENaC activity in Cyp2c44(-/-) mice was attributed to the absence of Cyp2c44 epoxygenase activity, because 100 nmol/L if 11,12-EET (Cyp2c44 AA metabolite) blocked ENaC in the CCD of Cyp2c44(-/-) mice on both control and HK diets (data not shown). These results identify Cyp2c44 as the epoxygenase responsible for the increases in 11,12-EET biosynthesis of the CCD in response to an HK intake.

Because non-Cyp2c44 epoxygenases are also expressed in the CCD,20 we next examined whether the inhibitory effects of AA on ENaC were Cyp2c44 dependent by analyzing ENaC responses to AA in the CCD dissected from wt or Cyp2c44(-/-) mice fed a control K or HK diet. Figure 2A is a channel recording in a cell-attached patch showing that the application of AA (15 µM) did not inhibit ENaC activity in Cyp2c44(-/-) mice. In 10 similar experiments, the channel activity, defined by NPo (a product of channel number [N] and open probability [Po]), was not significantly different (1.94±0.6) in the presence of or in the absence of AA (10–15 µmol/L; 1.8±0.6; Figure 2B). In contrast, increasing K content from 1.0% to 2.5% enhanced AA-mediated inhibition of ENaC in the wt mice. Data summarized in Figure 2B demonstrate that application of AA (10 µmol/L) inhibited ENaC activity from 0.87±0.04 to 0.4±0.06 (Figure 2B, top) or by 52±5% (Figure 2B, bottom) in the wt mice on a control K diet (N=8) and reduced NPo from 1.9±0.4 to 0.23±0.06 or by 88±10% in the animals fed an HK diet (N=8). The lack of an AA effect on the ENaC activity in Cyp2c44(-/-) mice was attributed to the absence of Cyp2c44 epoxygenase activity, because 100 nmol/L if 11,12-EET (Cyp2c44 AA metabolite) blocked ENaC in the CCD of Cyp2c44(-/-) mice on both control and HK diets (data not shown). These results identify Cyp2c44 as the epoxygenase responsible for the increases in 11,12-EET biosynthesis of the CCD in response to an HK intake.
findings are consistent with the previous report that AA-mediated inhibition of ENaC was enhanced in the CCD of rats on a 10% K diet.15 Taken together, the results suggest that Cyp2c44 is the epoxygenase responsible for mediating the effect of AA on ENaC in the mouse CCD.

We next examined whether Cyp2c44-dependent AA metabolism was involved in controlling ENaC basal activity by measuring the amiloride-sensitive Na currents in principal cells with perforated whole-cell recordings in the CCD of wt and Cyp2c44(−/−) mice on an HK diet for 3 to 7 days. We suspect that inhibition of CYP epoxygenase might increase ENaC activity if Cyp2c44 is involved in regulating channel basal activity. Figure 3A is a whole-cell recording showing that treatment of principal cells with N-methylsulfonyl-6-(2-propargyloxyphenyl)hexanamide (MS-PPOH; 5 μmol/L) on the amiloride-sensitive whole-cell Na currents in the principal cell of the cortical collecting duct (CCD) measured with the whole-cell recording at −100 to 60 mV with 20-mV step in wild-type (wt) or Cyp2c44(−/−) mice on a high-K (HK) diet. The trace was subtracted amiloride-sensitive Na currents. A current/voltage (I/V) curve demonstrating the effect of inhibiting CYP epoxygenase on the whole-cell, amiloride-sensitive Na currents in principal cells of the CCD in wt mice (Figure 3B, left) and in Cyp2c44(−/−) mice (Figure 3B, right). From inspection of Figure 3A, it is apparent that the disruption of the Cyp2c44 gene increased amiloride-sensitive Na currents in principal cells from 246±50 pA (wt mice) to 482±90 pA (P<0.05) at −100 mV (Cyp2c44(−/−) mice). Furthermore, inhibition of CYP epoxygenase with N-methylsulfonyl-6-(2-propargyloxyphenyl) hexanamide failed to increase Na currents in Cyp2c44(−/−) mice (489±140 pA at −100 mV). Similar results were observed in the mice fed a normal diet (1.0% K+0.3% Na; please see Figure S3). Inhibition of epoxygenase increased whole-cell Na currents in wt mice but had no effect in Cyp2c44(−/−) mice. Therefore, results strongly suggest that Cyp2c44-dependent AA metabolism is responsible for suppressing ENaC activity in principal cells of the wt mice fed an HK diet.

Because ENaC activity is upregulated in the CCD from Cyp2c44(−/−) mice on an HK diet, it is conceivable that increasing dietary K intake may enhance renal Na absorption or decrease the renal Na excretion in the mice containing the disrupted Cyp2c44 gene. Thus, we measured the food intake and urinary excretion of Na and K over a 24-hour period with metabolic cages in the wt and Cyp2c44(−/−) mice fed a normal K diet for 3 days and then fed an HK diet for an additional 3 days. Results summarized in Figure 4 show the 24-hour dietary Na intake and urinary Na excretion (UNa) in the wt and Cyp2c44(−/−) mice on a normal K diet (Figure 4, left) and on an HK diet (Figure 4, right). It is apparent that the ratios between UNa and dietary Na intake were not significantly different between wt and Cyp2c44(−/−) mice.
fed a normal K diet for 3 days (0.75 ± 0.04 and 0.68 ± 0.04 for wt and Cyp2c44-/- mice, respectively; N=8). These results suggest that disruption of the Cyp2c44 does not significantly alter renal Na handling in animals under control conditions. However, when fed an HK diet, UNa for Cyp2c44(-/-) mice was significantly lower than that of wt animals. The ratio for day 3 between UNa and Na intake for 24 hours decreased from 0.68 ± 0.04 (control diet) to 0.43 ± 0.04 (HK diet; N=8) in Cyp2c44(-/-) mice, whereas the ration was unchanged in the wt animals on an HK diet (0.76 ± 0.04). Therefore, lack of a functional Cyp2c44 epoxypgenase impairs the renal ability to excrete Na during increasing dietary K intake. Next, we used a similar experimental protocol to examine whether the urinary excretion of K was altered in mice carrying a disrupted Cyp2c44 gene. Figure 5 summarizes experiments in which 24-hour dietary K intake and 24-hour urinary K excretion were examined in wt (N=8) and in Cyp2c44(-/-) mice (N=8) on a normal K or on an HK diet. From inspection of Figure 5, it is apparent that disruption of the Cyp2c44 gene did not significantly affect renal ability of K secretion under both control conditions and during an HK intake. The ratios between 24-hour urinary K excretion and K intake in mice on an HK diet for day 3 were 0.65 ± 0.04 (wt) and 0.8 ± 0.04 Cyp2c44(-/-), respectively. The notion that disruption of the Cyp2c44 gene impairs Na but not K excretion during increased dietary K intake is
The systolic blood pressure (BP) was measured with tail-cuff methods, and the value represents a mean value of measurements obtained from 3 to 5 mice. *Significant difference between 2 groups.

**Figure 6.** A, Effect of dietary K intake on the plasma Na concentration in the wild-type (wt) and Cyp2c44(-/-) mice (KO). B, Effect of increasing K intake from 1.0% to 2.5% on body weight of the wt and Cyp2c44(-/-) mice (KO).

**Figure 7.** A, Effect of increasing K intake on systolic blood pressure (BP) in the wild-type (wt) and Cyp2c44(-/-) mice. Mice were fed with normal salt (0.3% NaCl/1.0% KCl) or a high-K (HK) diet (0.3% NaCl/2.5% KCl). The BP was measured with carotid artery catheter (N=8). B, Effect of an HK intake on the BP of wt and CYP2C44+/+ and CYP2C44-/-.
Moreover, the HK-induced hypertension in Cyp2c44(/−/−) mice was the results of high ENaC activity, because application of amiloride (0.5 mg/100 g body weight) abolished the effect of an HK diet on the BP in Cyp2c44(/−/−) mice (Figure 7B).

Discussion

It is well documented that metabolism of AA by CYP epoxygenases plays a role in preventing salt-sensitive hypertension in animal models. A high salt intake has been shown to stimulate Cyp2c23 expression in rats, and a decrease in renal epoxygenase activity and urinary EETs levels is related to hypertension in Dahl rats. CYP epoxygenase metabolites may prevent salt-sensitive hypertension by modulating renal hemodynamics and by inhibiting renal Na transport. It has been reported that 11,12-EET regulates glomerular afferent arterioles, thereby possibly increasing glomerular filtration rate and facilitating Na excretion. In addition, inhibition of renal Na absorption by the CYP-epoxygenase–dependent AA metabolism could play a role in preventing the salt-sensitive hypertension. For instance, 5,6-EET has been shown to decrease Na absorption in the CCD by inhibiting the Na/H exchanger in the rabbit kidney. We have demonstrated previously that CYP-epoxygenase–dependent AA metabolites inhibited ENaC activity in the CCD and that 11,12-EET mediated the inhibitory effect of AA on ENaC activity. The effect of 11,12-EET was specific because EETs other than 11,12-EET had either no effect or exerted a modest inhibitory effect on ENaC. The role of CYP epoxygenase in preventing salt-sensitive hypertension has been documented in Cyp4a10(/−/−) mice that developed hypertension when fed a high-salt diet and have impaired regulatory control of their Cyp2c44 epoxygenase by dietary salt. Two lines of evidence strongly suggest that defective regulation of ENaC by epoxygenase-dependent AA metabolism was responsible for the salt intake–induced hypertension in Cyp4a10(/−/−) mice: patch-clamp experiments demonstrated that AA failed to inhibit, whereas 11,12-EET was able to block ENaC in the CCD of Cyp4a10(/−/−) mice, and inhibition of ENaC with amiloride abolished the salt-sensitive hypertension in Cyp4a10(/−/−) mice on a high-salt diet.

Although the role of CYP-epoxygenase–dependent AA metabolism in regulating ENaC is well established, it is still not understood which CYP epoxygenase is mainly responsible for regulating ENaC activity. Disruption of the Cyp4a10 gene compromised renal EET biosynthesis, suggesting that epoxygenases other than Cyp2c44 could also be downregulated in Cyp4a10(/−/−) mice. Three lines of evidence strongly suggest that Cyp2c44 is the epoxygenase responsible for mediating the inhibitory effect of AA on ENaC activity: (1) the whole-cell Na current in the principal cell of the CCD was significantly higher in Cyp2c44(/−/−) mice than those of the wt mice; (2) inhibition of epoxygenase increased ENaC activity in the wt but not in Cyp2c44(/−/−) mice; (3) AA failed to inhibit, whereas 11,12-EET blocked ENaC activity in Cyp2c44(/−/−) mice. These results strongly indicate that Cyp2c44 is the epoxygenase responsible for mediating AA-induced inhibition of ENaC.

In addition to high salt intake, our previous and present studies have also demonstrated that an HK intake stimulates the expression of Cyp2c44 in the kidney, especially in the CCD. Moreover, the effect of an HK intake on Cyp2c44 was specific, because an HK intake failed to increase CYP2J2 expression, which is expressed in the CDD. The observation that an HK intake failed to increase 11,12-EET/DHET generation in the isolated CCD of Cyp2c44(/−/−) mice strongly suggests that Cyp2c44 is the epoxygenase responsible for mediating the effect of an HK intake on 11,12-EET generation.

Increasing dietary K intake is expected to stimulate aldosterone secretion, which activates Na-K-ATPase and ENaC activity in aldosterone-sensitive distal nephron (ASDN). However, a high aldosterone induced by a high K diet did not increase renal Na absorption in ASDN and did not cause hypertension. Instead, increased dietary K intake facilitated renal Na excretion and decreased BP. This is partially attributed to a decrease in Na-Cl cotransport expression in the distal convoluted tubule, thereby reducing Na absorption in the distal convoluted tubule. In addition, we suggest that the HK-induced antihypertensive and natriuretic effects critically depend on Cyp2c44-dependent AA metabolism in the ASDN. The notion is supported by 3 lines of evidence: (1) increasing dietary K content from 1.0% to 2.5% raises the BP in Cyp2c44(/−/−) mice but not in the wt mice; (2) the 24-hour UNa was lower in Cyp2c44(/−/−) mice on an HK diet than those of wt animals on an HK diet; (3) plasma Na concentrations and body weight were significantly higher in Cyp2c44(/−/−) mice on an HK diet than those of the wt mice. We hypothesize that an HK intake specifically stimulates Cyp2c44 expression in the ASDN, including CCD (please see Figure S5). Increased Cyp2c44 expression enhances AA metabolism to generate 11,12-EET, which inhibits ENaC. Therefore, we propose that, although an HK intake increases plasma aldosterone levels, which stimulate ENaC expression and Na-K-ATPase, the HK intake–induced increase in 11,12-EET biosynthesis suppresses ENaC activity, thereby facilitating Na excretion in ASDN and preventing hypertension. However, it is possible that a mechanism other than stimulation of ENaC activity may also contribute to the HK intake–induced increase in BP in Cyp2c44(/−/−) mice. It has been reported that an HK intake increased the plasma vasopressin concentration in male rats. Further experiments are required to explore whether a high vasopressin level is also responsible for raising the BP in animals with downregulated epoxygenase activity.

Another finding of the present study is that Cyp2c44 disruption did not affect the renal ability to excrete K, because the ratios between 24-hour urinary K secretion and dietary K intake in Cyp2c44(/−/−) mice were similar to those wt mice under control conditions and during an HK adaptation. We have demonstrated previously that 11,12-EET activates the Ca2+-dependent big-conductance K (BK) channel in the CCD, thereby mediating BK channel–dependent and flow-stimulated K secretion. Two factors may play a role in stimulating K secretion in Cyp2c44(/−/−) mice. First,
an HK intake is known to stimulate renal outer medullary potassium channel expression,32–34–36 thereby compensating for the function of BK channels. Relevant to this proposal was the report that renal K secretion was not compromised in BK channel knockout mice.37 Second, increased ENaC activity in Cyp2c44(−/−) mice augments the driving force for K secretion through renal outer medullary potassium channels. Thus, although a decrease in 11,12-EET generation is expected to diminish the BK channel activity, K secretion in Cyp2c44(−/−) mice is normal through increasing renal outer medullary potassium channel activity and enhanced driving force for K secretion.

In summary, the present study demonstrated that 11,12-EET generated by Cyp2c44 is involved in suppressing renal Na transport in the ASDN during increasing dietary K intake. We conclude that Cyp2c44-dependent AA metabolism plays a key role in mediating the HK-induced antihypertensive effect and also in promoting renal Na excretion.

Perspectives

The present study suggests a potential caveat to increase K intake for people who have defective CYP epoxygenase function because of genetic or pharmacological reasons, because an HK intake could possibly result in dietary K-sensitive hypertension. In this regard, it has been reported that polymorphisms of human Cyp2c8 and Cyp2c9 genes (functional homologues of Cyp2c44) result in a low epoxygenase activity.38 Thus, the present study has physiological and clinical importance, because it will provide guidance for the K supplement.

Methods

Animals: Isogenic Cyp2c44(-/-) and Cyp2c44(+/+) mice were obtained from Dr. J. Capdevila, Vanderbilt University. Global Cyp2c44 mouse knockouts (50:50 C57Bl/6 albino/129 SvE) from Lexicon Genetics Inc (Texas) were derived from an Ommibank ES (129SeV) cell line (clone OST85045) in which, insertion of a viral gene trap at exon 4 of Cyp2c44 (66 bp from the upstream intro/exon boundary) generates truncated, non-coding, Cyp2c44 transcripts. These animals were crossed with Cyp2c44(+/+)(129SeV)(Taconic Farms, NY) to generate homozygous Cyp2c44(+/+) and Cyp2c44(-/-) mice in isogenic 129/SeV backgrounds from the progeny of an F15 cross of heterozygous Cyp2c44(+/-) mice. Tail DNAs were genotype by PCR with primers flanking the trap insertion site (forward, 5'-caccttcatcctggcctgtg-3'; reversed, 5'-ttacgactgagccacattcc-3'), and a primer specific for the 3'-end of the viral trap (forward, 5'-ggcgttacttaagctagcttgc-3').

Dissecting CCD and patch-clamp Several thin slices of the kidney (<1 mm) were cut and placed on an ice-cold Ringer solution. After the isolation of the CCDs, they were placed on a 5 x 5mm cover-glass coated with polylysine and then transferred to a chamber (1000 μl) mounted on an inverted Nikon microscope. The CCD was cut open with a sharpened micropipette to expose the apical membrane and was superfused with HEPES buffered NaCl solution. A borosilicate glass (1.7-mm OD) was used to make the patch-clamp pipettes that were pulled with a Narishege electrode puller. An Axon200B patch-clamp amplifier was used to record the channel current. The currents were low-pass filtered at 50 Hz and digitized by an Axon interface (Digidata 1322). Data were analyzed using the pClamp software system 9 (Axon). Channel activity, defined as NPo, was calculated from data samples of 60 seconds duration in the steady state as follows:

\[
NP_o = \sum (t_1 + 2t_2 + \ldots + t_i)
\]

where \( t_i \) is the fractional open time spent at each of the observed current levels. If we compare the channel activity between the mice with different treatments, we normalized data by taking the initial control values.
as 100%. The pipette solution for studying Na channels contained (in mM) 140 NaCl, 1.8 MgCl₂, 1.8 CaCl₂ and 5 HEPES (PH=7.4). The bath solution for single channel patch-clamp experiments contained (in mM) 135 NaCl, 5 KCl, 1.8 CaCl₂, 1.8 MgCl₂, 2 glucose and 10 HEPES (pH=7.4).

For the whole-cell clamp measurements, The CCDs were superfused with solutions containing (in mM) 135 Na methanesulfonate, 5 KCl, 2 CaCl₂, 1 MgCl₂, 2 glucose, 5 mM BaCl₂, and 10 HEPES adjusted to pH 7.4 with NaOH. The tip of the pipette was filled with pipette solution followed by back-filling with amphotericin B (2 μg/0.1 ml) containing the pipette solution which was composed of (in mM) 7 KCl, 123 aspartic acid, 20 CsOH, 20 TEAOH, 5 EGTA, 10 HEPES, 3 MgATP, and 0.3 NaGDP-BS with the pH adjusted to 7.4 with KOH. The whole-cell Na current was determined by adding 10 μM amiloride in the bath solution. Data were analyzed using the pClamp software system 9.0 (Axon).

**Tissue preparation and Western blot**

The renal cortex and outer medulla were separated under a dissecting microscope and suspended in RIPA solution (1:8 ratio, w/v) containing 50 mM Tris-HCl (pH=7.4), 10 mM NaCl, 1% NP-40, 1% Triton X-100, 0.1% SDS, 1 mM sodium molybdate, 1 mM para-nitrophenyl-phosphate and 1mM EDTA. For every 125 mg tissue sample, we added 25 μl cocktail of protease and phosphatase inhibitors containing aprotinin (1 μg/ml), leupeptin (1 μg/ml), pepstatin A (1μg/ml), sodium vanadate (Na₃VO₄) (1.5 mM) and sodium fluoride (1 mM). The samples were left on ice for 15 min and homogenized with a mortar and pestle. The protein concentrations were measured twice using the Pierce BSA protein assay. The homogenized tissue samples were incubated in the presence of DNAse (5 μg/ml) and rabbit IgG serum at 4°C for 60 min. The mixture was then centrifuged at 3000 rpm for 10 min at 4°C and the resultant supernatant collected. The proteins were separated by electrophoresis on 10% SDS-polyacrylamide gels and transferred to nitrocellulose membrane. The membranes were blocked with 5% nonfat dry milk in Tris-buffered saline (TBS), rinsed and washed with 0.05% Tween20-TBS buffer. An Odyssey infrared imaging system (LI-COR, Lincoln, Nebraska) was used to scan the membrane at a wave-length of 680 or 800 nM.

**Measurement of EET:**

The isolated CCDs were placed in a tube containing ice-cold Na Ringer (0.5 ml). Eicosanoids in the tubule and media were acidified to pH 4.0 with 9% formic acid. We added 2 ng D₈ 11,12-EET in the tube as internal standard, the samples were extracted twice with 2X vol. ethyl acetate. Ethyl acetate extract was evaporated to dryness and the lipid residue was subsequently resuspended in methanol. After extraction, the CCD tubules were homogenized and the protein concentration was measured. The samples were purified by reverse phase (RP)-HPLC on a C₁₈ μBondapak column (4.6 X 24 mm) using...
a linear gradient from acetonitrile:water:acetic acid (62.5:37.5:0.05%) to acetonitrile (100%) over 20 min at a flow rate of 1 ml/min. The fraction containing 11,12-EET was collected on the basis of the elution profile of standards monitored by ultraviolet absorbance (205 nm). The fractions were evaporated to dryness and resuspended in 100 μl of acetonitrile. HPLC fractions containing 11,12-EET were derivatized as described earlier(4). The derivatized 11,12-EET was dried with nitrogen and resuspended in 50 μl of iso-octane for gas chromatography-mass spectrometry (GC-MS) analyses. A 1 μl aliquot of derivatized CYP-derived AA metabolites, dissolved in iso-octane, was injected into a GC (Hewlett Packard 5890) column (DB-1ms; 10.0 m, 0.25 mm inner diameter, 0.25 μm film thickness, Agilent). We used temperature programs ranging from 150-300°C at rates of 25°C/min, respectively(16). Methane was used as a reagent gas at a flow resulting in a source pressure of 1.3 torr and the MS (Hewlett-Packard 5989A) was operated in electron capture chemical ionization mode. The endogenous 11,12-EET (ion m/z 319) was identified by comparison of GC retention times with authentic D8 11,12-EET (m/z 327) standards.
Results

Fig. S1 The urinary epoxygenase excretion (EETs+DHETs) in Cyp2C44+/+ and Cyp244-/- mice (left panel) (N=4). The bar graph in the right panel shows the ratio among 14,15-, 11,12-, and 8,9-EET/DHET in Cyp2C44+/+ and Cyp244-/- mice.
Fig. S2  A Western blot shows the expression of CYP4a10, Cyp4a12, Cyp4a14, Cyp2c29 and actin in the kidneys from Cyp2c44+/+ (wt) and Cyp2c44-/- mice (KO), respectively.
